Subject: Routing of fiber ribbons into cassettes

Introduction

Recent design discussions have resulted in the elimination of the fiber mixing box in favor of an electronic mixing box. This decision has the result that, instead of fibers grouped by sector, fibers grouped by ribbon are dropped into the cassettes. This document lays down some naming conventions to insure we all work off the same page.

General Numbering Scheme

The detector is cylindrical and consists of eight layers of ‘fibers’ (layers A through H) and one layer of ‘preshower fibers’. A polar coordinate scheme is used, where the angle Φ runs from 0 to 360 degrees. A crude sketch is shown as figure 1.

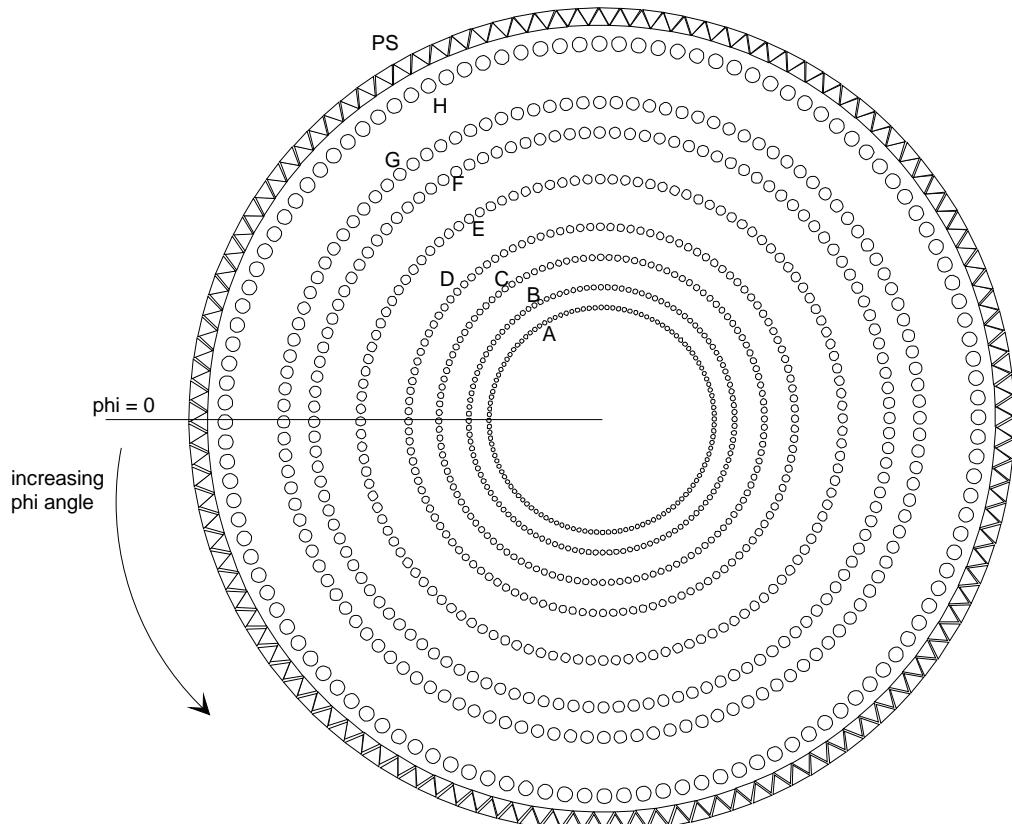

Figure 1

Each layer of fibers is stripped off the detector in ribbons of 256. These ribbons are loaded into the warm end connectors of the cassettes. A picture of one of the warm end connectors is given in Figure 2.

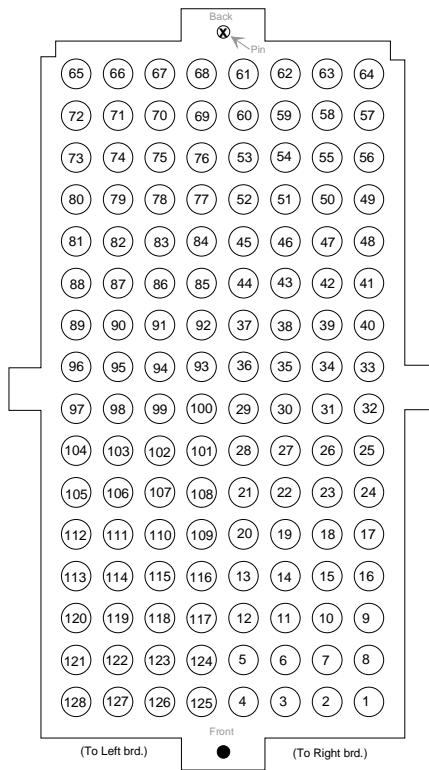

Figure 2

A single ribbon fills two connectors. The ribbon is cut in half and each half is wrapped in a serpentine pattern to fill the 128-pin optical connector. The lowest phi fiber of the ribbon is aligned to the left-most, rear-most pin of the rear-most connector of the pair.

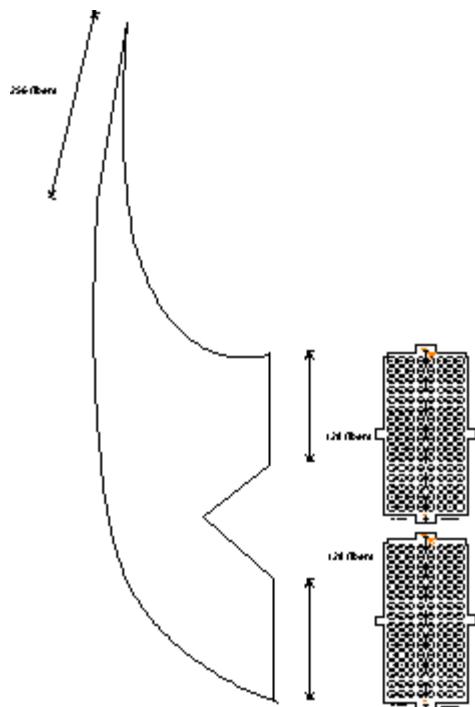

Figure 3

Within each of the 128-pin warm end connectors, the half of the ribbon is loaded in a serpentine pattern as shown in Figure 4.

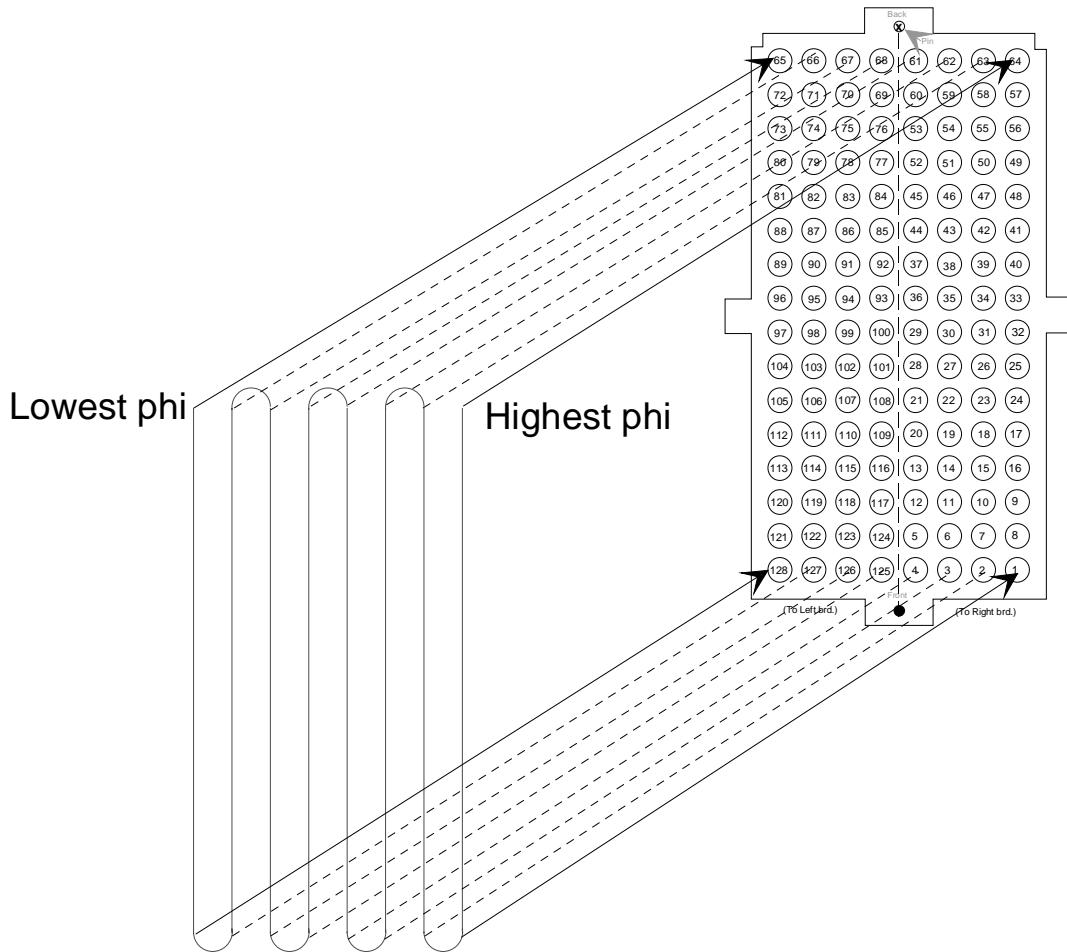

Figure 4

Table 1 shows an example for the 'A' layer of the detector, pictorially showing which fiber is landed in each position of two Warm End connectors.
